# Definition:

## River and Floodplain Processes...

The study of sediment sources, fluxes and storages within the river channel over short, medium and longer timescales and; of the resultant floodplain morphology (Sear and Newson, 1993).  
The pattern is determined by the hydrological regime in a natural system.

Helps to identify appropriate mitigation measure.

# Catchments

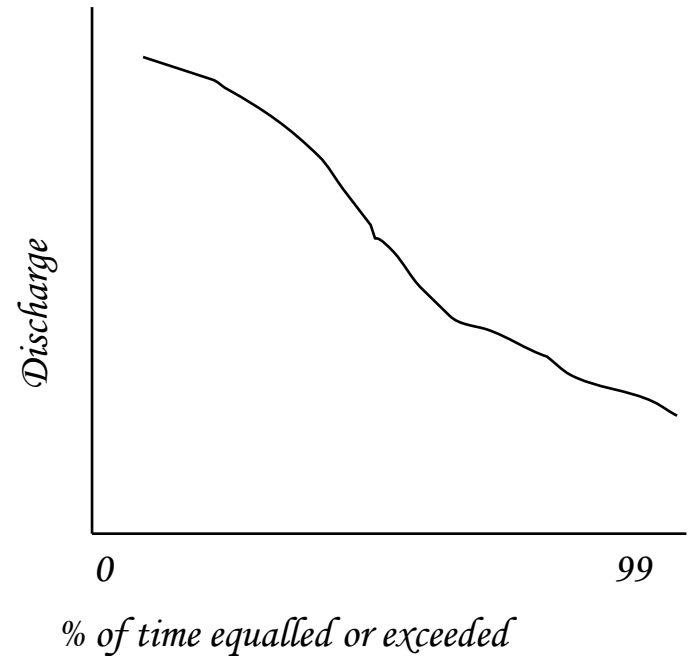

- Streams receive water from their drainage basin
- Discharge: related to catchment area plus other influences

# Discharge

- Discharge (cubic m/s). It has a magnitude-frequency relationship – both the very high and very low flows are rarer, the middle size flow more common
- Small flow is exceeded a lot of the time, a given high flow is rarely exceeded.
- Important because impact on how much sediment and associated pollutants will move in the system and where they will be transported to within the context of the catchment characteristic.

**the River Restoration Centre**

*Working to restore and enhance our rivers*

## **Types of Flow to the River**

- *Base or steady flow:* Slower route: rate depends on geology and landuse and flows through rather than over land.
- *Flashy or overland:* Catchments respond very quickly: depends on geology and human intervention.

Affects how quickly sediment, water and pollutants enter the river. Impact on aquatic habitat distribution and quality. Impacted by human intervention in the catchment

**the River Restoration Centre**

*Working to restore and enhance our rivers*

## Effects of Hydrology

- Catchments receive inputs (precipitation)
- Transformed to outputs (streamflow and evaporation)
- Input = output (allow for storage)
- Output is continuous.
- Inputs (precipitation) are discrete (i.e. separated by time/space).

*Note:*

- Visible and invisible inputs (e.g. seepage)
- Some river flow in summer maybe sustained by the flow of groundwater

River

... what characteristics can  
you see?

# Understanding connectivity in the sediment transfer system

Where are the sediment 'sources', 'transfers' and 'sinks'?.. Helps to identify risk

## UPLAND SUPPLY ZONE

Weathering  
100000 years

## SEDIMENT TRANSFER ZONE

Active bars  
9-26 years

Inactive bars  
c.100 years  
Main channel  
48 years

## LOWLAND SEDIMENT STORAGE ZONE

## "KNOCK-ON" EFFECT OF THE SEDIMENT SYSTEM

- ① Slope failure
- ↓
- ② Channel blockage
- ↓
- ③ Channel aggrades and banks erode
- ↓
- ④ Erosion of bank as bars accrete
- ↓
- ⑤ Build up on bank followed by collapse
- ↓
- ⑥ Erosion of banks due to slumping
- ↓
- ⑦ Conveyance loss of fines to floodplain
- ↓
- ⑧ Fines washed out to sea

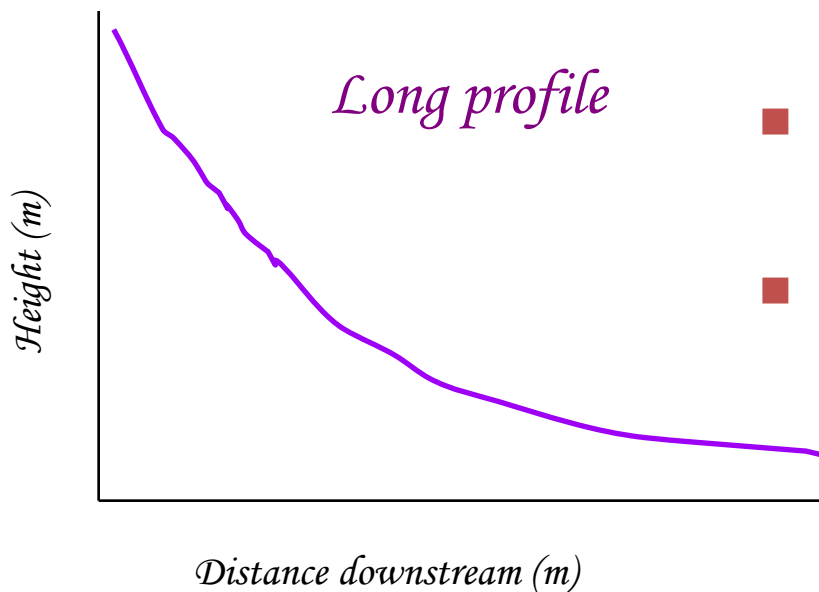

**the River Restoration Centre**

*Working to restore and enhance our rivers*

## Gradient or long profile (the energy curve)

Catchments naturally saucer shaped

- Steeper at the top - lots of energy but less catchment area so less discharge.
- Middle reaches - less gradient, more discharge from larger catchment.
- Lower reaches- lower gradient but highest discharge.

**So where you are in the catchment  
effects erosion/deposition  
characteristics**

# Hydrology/Hydraulics

**the River Restoration Centre**

*Working to restore and enhance our rivers*

# Relevance to River Restoration?

- River restoration can change the shape, size and slope of river reaches
- Has impact on the amount of water a channel carries
- Flood levels might change
- The flow characteristics might change – velocities, flow spilt down channel and on floodplain

Need to understand hydrology (how much water coming through the catchment) and impact on sediment movement to inform flood risk management and habitats

**the River Restoration Centre**

## **The Purpose of Hydraulics Studies?**

- Determine the level/depth and extent of the water, and the velocities in the channel and floodplain under normal and flood conditions:
  - Experience/anecdotal evidence of what has happened previously
  - Or.. Models... complexity used depends on what you need to know! (Risk of increase water levels)

## Hydraulics – Base Calculation (Mannings)

$$\bar{v} = \frac{R^{2/3} s^{1/2}}{n}$$

Where

$v$  = Mean flow velocity (m/s)

$R$  = Hydraulic radius

$s$  = Channel gradient (energy slope)

$n$  = Manning's roughness coefficient

**the River Restoration Centre**

*Working to restore and enhance our rivers*

## **How Does this Help us in Restoration Design?**

- Water levels within, upstream and downstream reach (flood, channel forming, normal)
- Some models = flood routes, flood flow rates and direction, flood storage
- Helps geomorphology design ( v profile and Q)
- Enables assessment of the impact on 3<sup>rd</sup> parties from works and provides required assurances

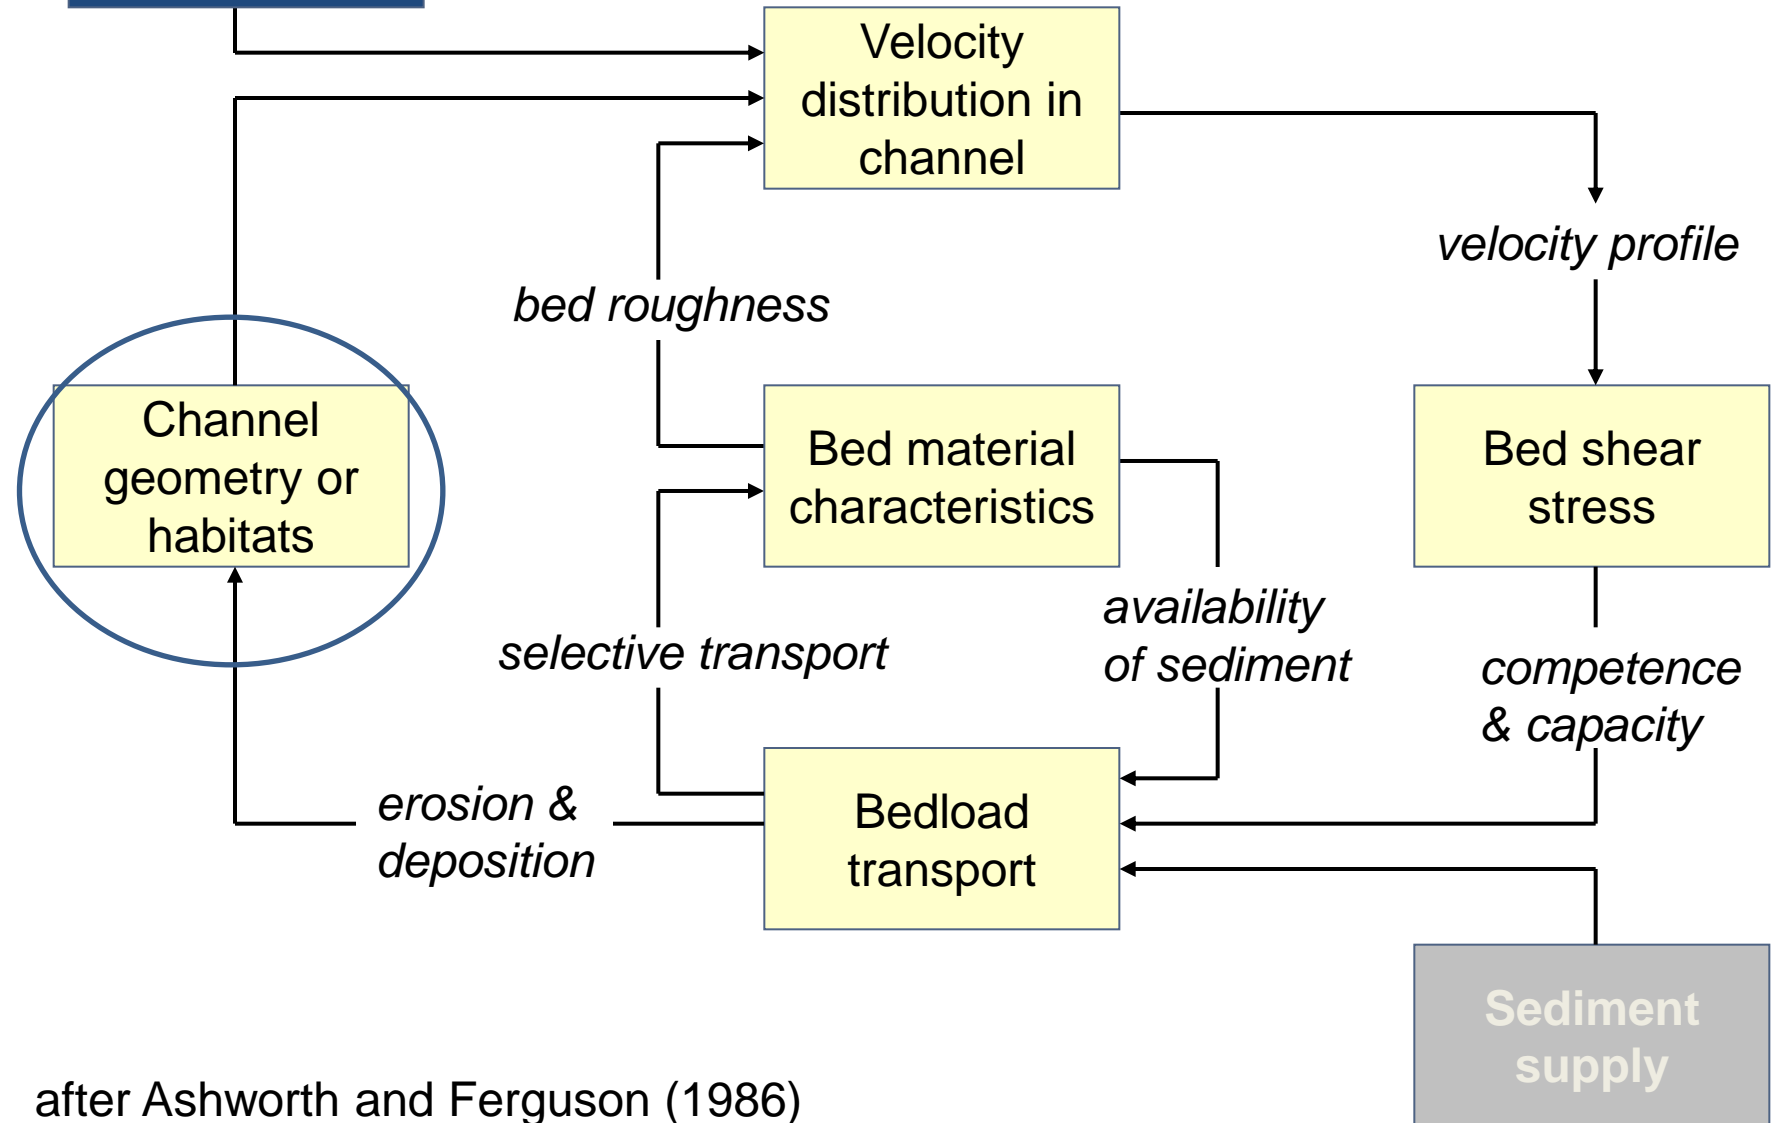

**the River Restoration Centre**

*Working to restore and enhance our rivers*

## **Comparison of Drainage and Restoration – impact on Hydraulics**

	<b><u>Drainage</u></b>	<b><u>Restoration</u></b>
<b>Aim</b>	<b>To drain away stormwater quicker, reduce water and flood levels</b>	<b>Restore more natural channel geomorphology, flows and features. Reconnect channel and floodplains</b>
<b>Impact on velocity and flow</b>	increased flow velocity, increased discharge	More variable velocity, more natural flows, less flow in channel
<b>Impact on Roughness Coefficient</b>	Reduced roughness (less vegetation, bed features and regular channel shape)	Restore more natural roughness or increase roughness
<b>Impact on Slope</b>	Increased (steeper) slope	Restore 'natural' bed profile considering sediment continuity
<b>Impact on Hydraulic Radius</b>	Increased (larger) channel width & depth area	Change channel dimensions to provide self sustaining in channel features

after Ashworth and Ferguson (1986)
